CONDITIONS WE TREAT

Your heart, explained in plain language.

Put your heart in the most experienced hands.

These are general guides, not a diagnosis. Professor Gupta will explain your own situation at an unhurried consultation.

Normal rhythm

AF

Atrial fibrillation (AF)

WHAT IT CAN FEEL LIKE

An irregular, often fast heartbeat

Some people feel nothing at all

Tiredness, breathlessness, or anxiety

WHAT IS HAPPENING

The upper chambers of your heart, the atria, beat in a disorganised way instead of a steady rhythm. Blood does not move through as smoothly, which is why AF raises stroke risk if left unmanaged.

HOW PROFESSOR GUPTA CAN HELP

Professor Gupta has treated atrial fibrillation for more than thirty years and performs over 200 ablation procedures a year. At your consultation he will explain what is happening in your heart, whether a procedure is right for you, and which technology suits your situation, in plain language.

See why experience matters !'

Normal rhythm

Atrial flutter

Atrial flutter

WHAT IT CAN FEEL LIKE

A fast but usually very regular heartbeat, often 130-150 beats per minute

A fluttering, pounding, or racing sensation in the chest

Breathlessness, tiredness, or lightheadedness, especially on exertion

WHAT IS HAPPENING

In atrial flutter, the upper chambers of your heart do not beat chaotically as they do in AF. Instead, one electrical signal races round a fixed circuit, usually in the right atrium, in a fast, regular loop. This is why the pulse in atrial flutter often feels very steady, just very fast. Like AF, it can allow blood to pool and clot in the heart, so it carries a similar stroke risk and is assessed the same careful way.

HOW PROFESSOR GUPTA CAN HELP

Because the electrical circuit follows a predictable, mappable path, atrial flutter often responds very well to catheter ablation, a small procedure that interrupts the loop at one precise point. Professor Gupta will confirm the diagnosis with an ECG, explain how likely ablation is to work for your specific type of flutter, and discuss whether blood-thinning treatment is also needed.

Normal rhythm

SVT

Supraventricular tachycardia (SVT)

WHAT IT CAN FEEL LIKE

Sudden episodes of a very fast heartbeat, sometimes over 150 beats per minute

A racing heart that starts and stops abruptly, sometimes without warning

Chest discomfort, breathlessness, or lightheadedness while an episode lasts

WHAT IS HAPPENING

SVT is a general term for fast rhythms that start above the heart's main pumping chambers. Most often, it is caused by an extra electrical pathway, present since birth, that lets signals loop back on themselves and briefly take over the heartbeat. Episodes tend to begin and end suddenly, lasting anywhere from seconds to hours, and can happen at any age.

HOW PROFESSOR GUPTA CAN HELP

Most types of SVT can be located precisely with a heart rhythm test called an electrophysiology study, and treated in the same sitting with catheter ablation, often ending the problem for good. Professor Gupta will explain which type of SVT you have, how likely ablation is to succeed for it, and what the day of the procedure involves.

Normal rhythm

Palpitations

Palpitations & unexplained heart racing

A symptom, not a single diagnosis. Many possible causes.

WHAT IT CAN FEEL LIKE

A sudden awareness of your own heartbeat, fluttering, pounding, or thumping

A sense that your heart has skipped a beat or added an extra one

Racing that appears with no obvious trigger, or lingers after exercise or stress has passed

WHAT IS HAPPENING

Palpitations describe a noticeable heartbeat, they are a symptom, not a diagnosis in themselves. Often the cause is entirely harmless, caffeine, alcohol, anxiety, or hormonal changes can all bring them on. Sometimes, though, they are the first sign of an underlying rhythm problem such as AF, atrial flutter, SVT, or extra "ectopic" beats. Working out which it is starts with recording what your heart is actually doing while you feel the symptom.

HOW PROFESSOR GUPTA CAN HELP

Professor Gupta will take a careful history, then usually arrange an ECG and a period of heart rhythm monitoring, sometimes a few days, sometimes longer, to capture an episode as it happens. Once there is a clear diagnosis, he will explain in plain language exactly what is going on and which treatment, if any, fits your situation.

Normal rhythm

Pause

Unexplained blackouts & dizziness

A symptom, not a single diagnosis. Many possible causes.

WHAT IT CAN FEEL LIKE

Sudden loss of consciousness (syncope), with or without any warning

Lightheadedness, dizziness, or a feeling that the room is spinning

A near-blackout that passes after a few seconds, sometimes with pale skin or sweating

WHAT IS HAPPENING

A blackout happens when blood flow to the brain briefly falls, often because the heart beats too slowly, pauses, or occasionally too fast, to keep up with demand. Not every blackout is heart-related, simple faints and low blood pressure are common and usually harmless, but some are caused by significant rhythm problems that carry a real risk if they go unrecognised, which is why unexplained blackouts deserve a proper cardiac assessment.

HOW PROFESSOR GUPTA CAN HELP

Professor Gupta will look for a rhythm problem around the time your blackouts happen, using ECG monitoring and, where needed, a small implantable loop recorder that watches your heart continuously for months at a time. If a cause such as bradycardia or heart block is found, he will explain clearly whether a pacemaker or another treatment is the right next step.

Normal rhythm

Bradycardia

Bradycardia (slow heart rhythms)

WHAT IT CAN FEEL LIKE

A resting heart rate that stays persistently below 60 beats per minute

Tiredness, breathlessness, or a reduced ability to exercise

Dizziness, lightheadedness, or blackouts if the rhythm slows further

WHAT IS HAPPENING

Bradycardia means the heart's natural pacemaker, or the electrical wiring that carries its signal onward, is firing too slowly or being partly blocked along the way. A slow heart rate is completely normal in fit, healthy people and during sleep, but a persistently slow or pausing rhythm can mean the heart is no longer pumping enough blood to meet the body's needs.

HOW PROFESSOR GUPTA CAN HELP

Professor Gupta will establish whether your slow rhythm is a normal variant or something that needs treatment, usually with an ECG and a period of heart rate monitoring. Where a pacemaker is the right answer, he will explain in plain language how it works, what the procedure to fit one involves, and what daily life with one is like afterwards.

Every heart is different.

If something here sounds familiar, book a consultation. Professor Gupta will review your history and explain what is happening in plain language, in English, Hindi, or Punjabi.
